Motivation

To reduce the vulnerability to a debt crisis:

- Should the government reduce the debt or increase reserves?

Motivation

To reduce the vulnerability to a debt crisis:

- Should the government reduce the debt or increase reserves?

Answer unclear:

- Reserves provide liquidity, but their return is lower than borrowing costs

What we do

- Tractable model of rollover crises with long-duration bonds and reserves
 - Sunspot shocks, deterministic income
- How should the government exit the 'crisis zone'?

What we do

- Tractable model of rollover crises with long-duration bonds and reserves
 - Sunspot shocks, deterministic income
- How should the government exit the 'crisis zone'?

Preview:

- If heavily indebted, optimal to initially reduce debt and keep zero reserves
- Once debt is reduced sufficiently, optimal to increase debt and accumulate reserves
- Borrowing to accumulate reserves can reduce spreads

What we do

Model

Environment

- Discrete time, infinite horizon. Constant endowment: $y_t = y$
- Government trades two assets ...
 - short-term risk-free reserves, a
 - long-term defaultable debt, b
a bond issued in t promises to pay

$$\kappa [1, (1 - \delta), (1 - \delta)^2, \dots]$$

- Risk-neutral deep pocket international investors:
 - Discount future flows at rate r , assume $\beta(1 + r) = 1$

Environment

- Discrete time, infinite horizon. Constant endowment: $y_t = y$
- Government trades two assets ...
 - short-term risk-free reserves, a
 - long-term defaultable debt, b
a bond issued in t promises to pay

$$\kappa [1, (1 - \delta), (1 - \delta)^2, \dots]$$

- Risk-neutral deep pocket international investors:
 - Discount future flows at rate r , assume $\beta(1 + r) = 1$
- Markov equilibrium w/ Cole-Kehoe (2000) timing:
 - Borrowing at the beginning of the period
 - Settlement (repay/default) at the end

Preferences and resource constraint

- Preferences:

$$\mathbb{E}_0 \sum_{t=0}^{\infty} \beta^t [u(c_t) - \phi d_t]$$

where $d_t = 0$ (1) denotes repayment (default)

Preferences and resource constraint

- Preferences:

$$\mathbb{E}_0 \sum_{t=0}^{\infty} \beta^t [u(c_t) - \phi d_t]$$

where $d_t = 0$ (1) denotes repayment (default)

- If the government repays:

$$c_t = \underbrace{y + a_t - \kappa b_t}_{\text{resources avail.}} - \underbrace{\frac{a_{t+1}}{1+r}}_{\text{reserve purchases}} + \underbrace{q_t [b_{t+1} - (1-\delta)b_t]}_{\text{debt issuance}}$$

Preferences and resource constraint

- Preferences:

$$\mathbb{E}_0 \sum_{t=0}^{\infty} \beta^t [u(c_t) - \phi d_t]$$

where $d_t = 0$ (1) denotes repayment (default)

- If the government repays:

$$c_t = \underbrace{y + a_t - \kappa b_t}_{\text{resources avail.}} - \underbrace{\frac{a_{t+1}}{1+r}}_{\text{reserve purchases}} + \underbrace{q_t [b_{t+1} - (1-\delta)b_t]}_{\text{debt issuance}}$$

- If the government defaults:

$$c_t = y + a_t - \frac{a_{t+1}}{1+r} \quad \text{Gov. saves on bond payments}$$

and faces permanent exclusion and utility loss ϕ

Recursive Government Problem

- State is $s \equiv (a, b, \zeta)$
 ζ denotes an iid sunspot that coordinates the lenders
- The government chooses to repay or default

$$V(a, b, \zeta) = \max \{V_R(a, b, \zeta), V_D(a)\}$$

If indifferent, assume repay

Value of Default

$$V_D(a) = \max_{a' \geq 0} \{u(c) - \phi + \beta V_D(a')\}$$

subject to

$$c \leq y + a - \frac{a'}{1+r}$$

Value of Default

$$V_D(a) = \max_{a' \geq 0} \{u(c) - \phi + \beta V_D(a')\}$$

subject to

$$c \leq y + a - \frac{a'}{1+r}$$

- Given $\beta(1+r) = 1$, we have constant consumption

$$V_D(a) = \frac{u(y + (1-\beta)a) - \phi}{1-\beta}$$

Value of Repayment

Two cases, depending on whether the investors want to rollover the debt

If investors **want** to rollover:

$$V_R^+(a, b) = \max_{a' \geq 0, b'} \{u(c) + \beta \mathbb{E} V(a', b', s')\}$$

subject to

$$c = y + a - \frac{a'}{1+r} - \kappa b + q(a', b') (b' - (1-\delta)b)$$

Value of Repayment

Two cases, depending on whether the investors want to rollover the debt

If investors **want** to rollover:

$$V_R^+(a, b) = \max_{a' \geq 0, b'} \{u(c) + \beta \mathbb{E} V(a', b', s')\}$$

subject to

$$c = y + a - \frac{a'}{1+r} - \kappa b + q(a', b') (b' - (1 - \delta)b)$$

Bond price depends on the portfolio and reflects default prob:

$$q(a', b') = \frac{1}{1+r} \mathbb{E} [(1 - d(s')) (\kappa + (1 - \delta)q(a'', b'', s'))]$$

Value of Repayment

Two cases, depending on whether the investors want to rollover the debt

If investors **don't want** to rollover:

$$V_R^-(a, b) = \max_{a' \geq 0} \{u(c) + \beta \mathbb{E}V(a', (1 - \delta)b, s')\}$$

subject to

$$c = y + a - \frac{a'}{1+r} - \kappa b + \cancel{q(a', b')(b' - (1 - \delta)b)} \rightarrow 0$$

To pay debt, need to use reserves or cut consumption

Multiplicity of Equilibria

- Coordination failure may lead to self-fulfilling crises (Cole-Kehoe)

- If lenders expect...
 - ... repayment, then they rollover, and the govt repays
 - ... default, then they don't rollover, and the govt defaults

Characterization

Default thresholds

For a given level of reserves, two thresholds

Sunspot: government faces a run w/ prob π when initial portfolio (a, b) is in the crisis zone

The Three Zones

Proposition 2 establishes: $\frac{\partial b^-(a)}{\partial a} \geq \frac{\partial b^+(a)}{\partial a} > 0$

Escaping the Crisis Zone

How to Exit the Crisis Zone?

Remaining in the crisis zone is risky:

- in case of a run, the gov't defaults

But exiting is also costly:

- requires cutting consumption and improving NFA

How to Exit the Crisis Zone?

Remaining in the crisis zone is risky:

- in case of a run, the gov't defaults

But exiting is also costly:

- requires cutting consumption and improving NFA

What's the best exit strategy for a country that is in the crisis zone (but didn't face a run today) ?

- Accumulate reserves ($a \uparrow$) or reduce debt ($b \downarrow$)?

Possible Exit Paths

- For given reserves level:
less debt lowers vulnerability
- For given debt level:
more reserves lower vulnerability

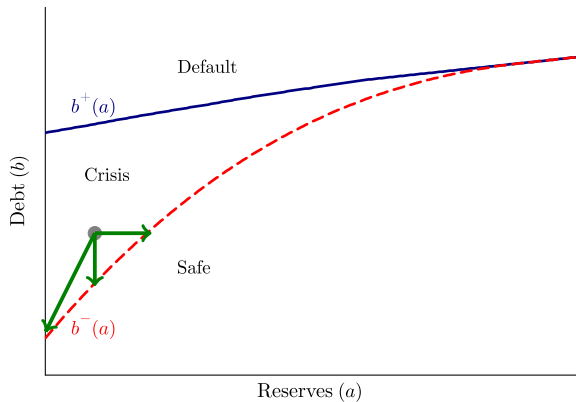

Possible Exit Paths

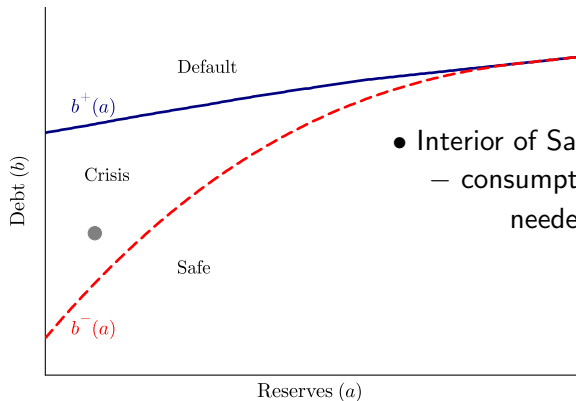

Possible Exit Paths

Possible Exit Paths

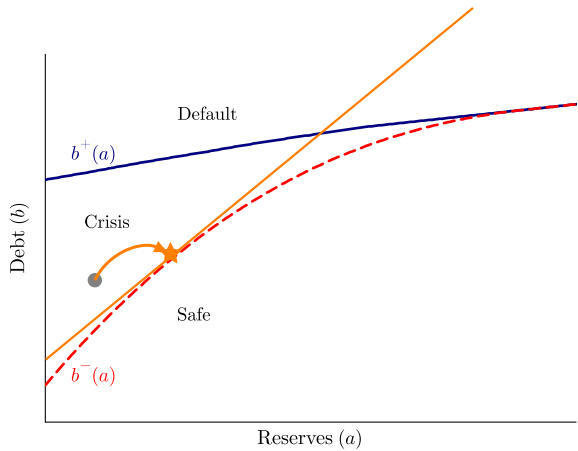

Possible Exit Paths

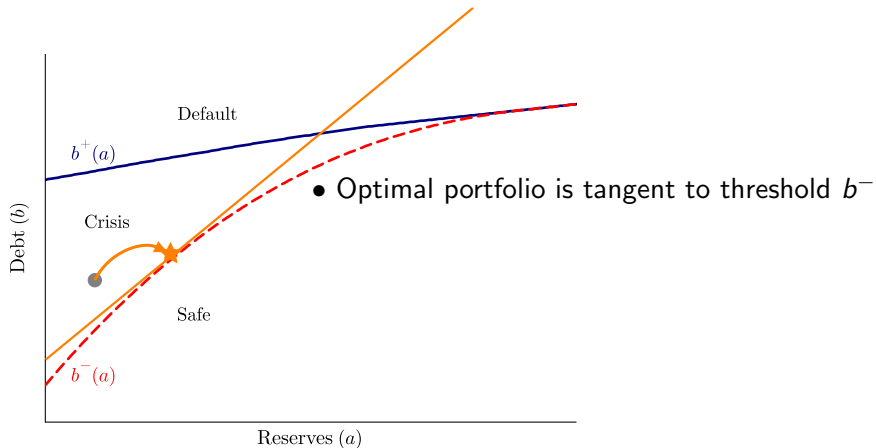

- Interior of Safe zone isn't optimal
– consumption cut larger than needed to be safe

Possible Exit Paths

Possible Exit Paths

Possible Exit Paths

Why do reserves help exit the crisis zone?

Getting to the safe zone requires $V_R^-(a, b) \geq V_D(a)$

- Accumulating reserves helps sustain higher net debt
... even though reserves increase default value $V_D(a)$.

Why do reserves help exit the crisis zone?

Getting to the safe zone requires $V_R^-(a, b) \geq V_D(a)$

- Accumulating reserves helps sustain higher net debt
- Only a fraction κ of debt is due every period
- Reserves are liquid and can be used in a run:

$$c = y + \underbrace{a - \kappa b}_{\text{more resources}} - \frac{a'}{1+r}$$

Why do reserves help exit the crisis zone?

Getting to the safe zone requires $V_R^-(a, b) \geq V_D(a)$

- Accumulating reserves helps sustain higher net debt
- Only a fraction κ of debt is due every period
- Reserves are liquid and can be used in a run:

$$c = y + \underbrace{a - \kappa b}_{\text{more resources}} - \frac{a'}{1+r}$$

- Reserves also make default more attractive, but have lower marginal value:

$$c_D = y + a - \frac{a'}{1+r}$$

Why do reserves help exit the crisis zone?

Getting to the safe zone requires $V_R^-(a, b) \geq V_D(a)$

- Accumulating reserves helps sustain higher net debt
- Only a fraction κ of debt is due every period
- Reserves are liquid and can be used in a run:

$$c = y + \underbrace{a - \kappa b}_{\text{more resources}} - \frac{a'}{1+r}$$

- Reserves also make default more attractive, but have lower marginal value:

$$c_D = y + a - \frac{a'}{1+r}$$

Borrowing to accumulate reserves reduces vulnerability

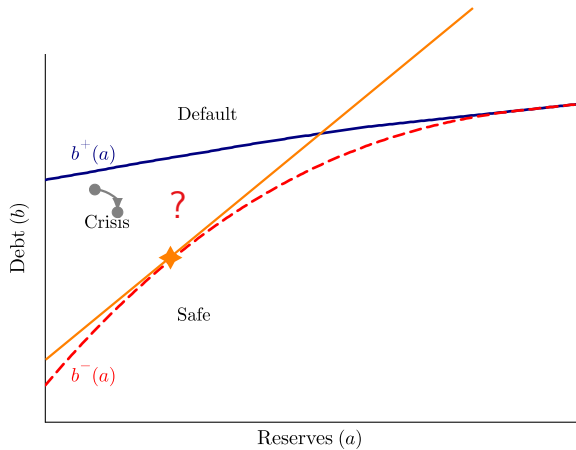

Deep in the Crisis Zone

Country has **higher** initial debt level: what to do?

Deep in the Crisis Zone

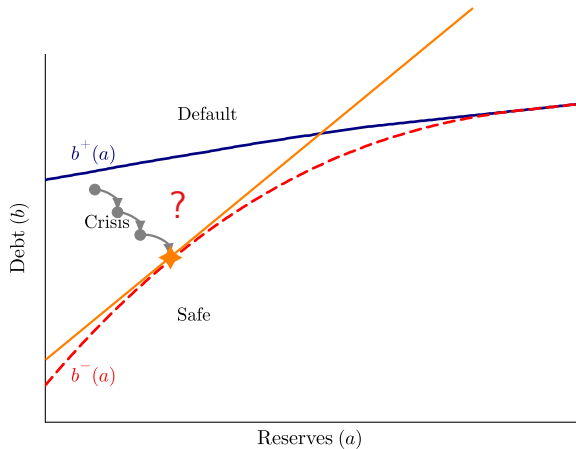

Deep in the Crisis Zone

Deep in the Crisis Zone

Deep in the Crisis Zone

Deep in the Crisis Zone

- Government sells reserves and lowers debt

Deep in the Crisis Zone

- Government keeps reducing debt

Deep in the Crisis Zone

- Government issues debt and buys reserves

Why selling reserves (initially)?

- When the government is 'deep' in the Crisis Zone, on the margin reserves do not change the probability of a run
- Using the reserves to lower debt allows the govt to save on interest payments and helps deleveraging

How many periods until exit?

Formalizing the Results: (a^*, b^*) portfolio

(a^*, b^*) is a focal point – we call it **Lowest-NFA safe portfolio**

When do we have $a^* > 0$?

Formalizing the Results: (a^*, b^*) portfolio

(a^*, b^*) is a focal point – we call it **Lowest-NFA safe portfolio**

When do we have $a^* > 0$?

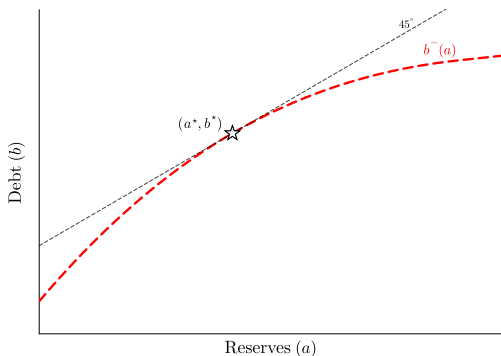

Answer: when $\left. \frac{\partial b^-(a)}{\partial a} \right|_{a=0} > 1$

Formalizing the Results: (a^*, b^*) portfolio

(a^*, b^*) is a focal point – we call it **Lowest-NFA safe portfolio**

When do we have $a^* > 0$?

Answer: when $\left. \frac{\partial b^-(a)}{\partial a} \right|_{a=0} > 1$

Lowest-NFA safe portfolio, (a^*, b^*)

(a^*, b^*) is a focal point. When do we have $a^* > 0$?

Answer: when $\left. \frac{\partial b^-(a)}{\partial a} \right|_{a=0} > 1$

Proposition 3 (Positive reserves)

Suppose that the boundary of the crisis region at zero reserves $b^-(0)$ satisfies

$$\beta(1-\delta) [u'(y - \kappa b^-(0)) - u'(y - (1-\beta)(1-\delta)b^-(0))] > u'(y)$$

Then, the lowest-NFA safe portfolio has strictly positive reserves, $a^* > 0$

Lowest-NFA safe portfolio, (a^*, b^*)

(a^*, b^*) is a focal point. When do we have $a^* > 0$?

Answer: when $\left. \frac{\partial b^-(a)}{\partial a} \right|_{a=0} > 1$

Proposition 3 (Positive reserves)

Suppose that the boundary of the crisis region at zero reserves $b^-(0)$ satisfies

$$\beta(1-\delta) [u'(y - \kappa b^-(0)) - u'(y - (1-\beta)(1-\delta)b^-(0))] > u'(y)$$

Then, the lowest-NFA safe portfolio has strictly positive reserves, $a^* > 0$

When does it fail?

1. low risk-aversion,

Lowest-NFA safe portfolio, (a^*, b^*)

(a^*, b^*) is a focal point. When do we have $a^* > 0$?

Answer: when $\left. \frac{\partial b^-(a)}{\partial a} \right|_{a=0} > 1$

Proposition 3 (Positive reserves)

Suppose that the boundary of the crisis region at zero reserves $b^-(0)$ satisfies

$$\beta(1-\delta) [u'(y - \kappa b^-(0)) - u'(y - (1-\beta)(1-\delta)b^-(0))] > u'(y)$$

Then, the lowest-NFA safe portfolio has strictly positive reserves, $a^* > 0$

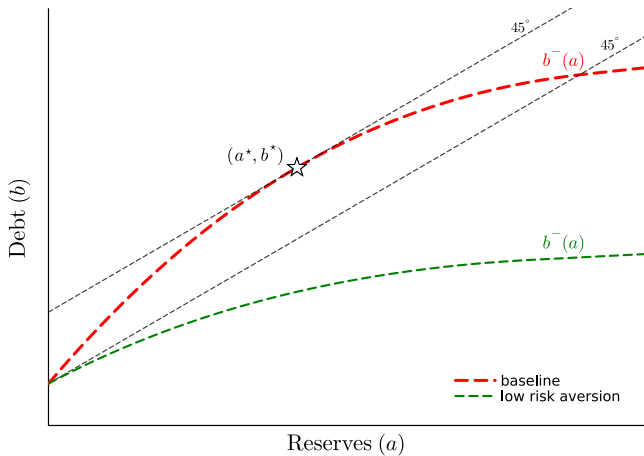

When does it fail?

1. low risk-aversion,
2. one-period debt ($\delta = 1$) [**Prop. 4**]

Lowest-NFA safe portfolio, (a^*, b^*)

Lowest-NFA safe portfolio, (a^*, b^*)

Formalizing the Results: Optimal portfolio

To exit crisis zone, first deleverage, then raise debt and reserves

Formalizing the Results: Optimal portfolio

To exit crisis zone, first deleverage, then raise debt and reserves

Proposition 5 (Optimal portfolio)

Consider an initial portfolio $(a, b) \in \mathbf{C}$. The optimal portfolio satisfies:

- If initial portfolio (a, b) is such that $a - b < a^* - b^*$ and $(a', b') \in \mathbf{S}$. Then we have $a' = a^*$, $b' = b^*$
- If initial portfolio (a, b) is such that $(a', b') \in \mathbf{C}$. Then, the optimal solution features $a' = 0$.

Formalizing the Results: Optimal portfolio

To exit crisis zone, first deleverage, then raise debt and reserves

Proposition 5 (Optimal portfolio)

Consider an initial portfolio $(a, b) \in \mathbf{C}$. The optimal portfolio satisfies:

- If initial portfolio (a, b) is such that $a - b < a^* - b^*$ and $(a', b') \in \mathbf{S}$. Then we have $a' = a^*$, $b' = b^*$
- If initial portfolio (a, b) is such that $(a', b') \in \mathbf{C}$. Then, the optimal solution features $a' = 0$.

Remark on maturity:

- **With one-period debt, $\delta = 1$:** V_R^- and V_R^+ are unaffected by equal increases in debt and reserves \Rightarrow issuing debt to accumulate reserves increases spreads
 - Zero reserves are optimal

Conclusions

- Simple theory of optimal res. management w/ rollover crises
- Optimal to accumulate reserves to reduce vulnerability
 - However, only after debt has been reduced towards safety

Conclusions

- Simple theory of optimal res. management w/ rollover crises
- Optimal to accumulate reserves to reduce vulnerability
 - However, only after debt has been reduced towards safety
- Reserves as 'buffer': after buildup, no use of reserves
 - Not using them doesn't mean they're unnecessary
- Issuing debt to accumulate reserves can reduce spreads

Conclusions

- Simple theory of optimal res. management w/ rollover crises
- Optimal to accumulate reserves to reduce vulnerability
 - However, only after debt has been reduced towards safety
- Reserves as 'buffer': after buildup, no use of reserves
 - Not using them doesn't mean they're unnecessary
- Issuing debt to accumulate reserves can reduce spreads
- Findings speak to policy discussions on appropriate level of FX reserves (e.g. IMF)
 - Following a debt crisis, IMF often prescribes increasing reserves
 - However, we find holding reserves not optimal at beginning of deleveraging process

THANKS!

Data: Government Debt and International Reserves

Government debt and reserves (as % of GDP), 2023

Evolution of Debt and Reserves

Avg. Government debt and reserves (as % of GDP)

- If $(a, b) \in \mathbf{S}$: we assume gov. stays in safe zone

$$V^S(a - b) = \frac{u(y + (1 - \beta)(a - b))}{1 - \beta}$$

- **Note:** relevant state variable is the NFA, $a - b$

For a high enough δ : can establish that gov. finds it optimal to stay in \mathbf{S}

- If $(a, b) \in \mathbf{C}$, govt. seeks to exit in finite time (may default along the way if bad sunspot hits)
 - Staying in the crisis zone implies eventually costly default
 - Speed of exit depends on curvature of $u(\cdot)$ and probability of bad sunspot

Continuation value:

$$\mathbb{E}V(a', b', \zeta') = \begin{cases} V^S(a' - b') & \text{if } (a', b') \in \mathbf{S} \\ (1 - \lambda)V_R^+(a', b') + \lambda V_D(a') & \text{if } (a', b') \in \mathbf{C} \\ V_D(a') & \text{if } (a', b') \in \mathbf{D} \end{cases}$$
